TABLE OF CONTENTS

SUMMARY	8
PART I PURPOSE AND AREA OF THE SURVEY.....	9
1. PURPOSE OF THE SURVEY.....	10
2. AREA OF THE SURVEY	11
Geography	11
History of Land-Use.....	11
PART II FEATURES OF THE NATURAL ENVIRONMENT	14
3. CLIMATE	15
Elements of the Climate	15
Rainfall	15
Temperature.....	17
Humidity and Evaporation	19
Interpretation for Pasture Growth.....	19
Effective Rain.....	19
Potential Evapo-Transpiration.....	20
Cold	22
Interpretation for Erosion Hazard.....	22
Summary	22
4. GEOLOGY AND PHYSIOGRAPHY	24
Parent Materials of the Soils.....	24
Palaeozoic Rocks.....	24
Cainozoic Rocks and Unconsolidated Sediments	24
Land-Forms	25
Plain.....	25
Swamp and Lunette	25
Ridge	25
Sand Dune	26
Sand Sheet	26
Stony Rise.....	26
Hill.....	26
Cuesta	26
Tableland	27
Geomorphological Units	27
Plains of Fluviate and Estuarine Sediments	28
Dunes and Sheets of Siliceous Sand.....	28
A Composite Sub-Division.....	30
Plains of Basalt.....	30
Lateritic Tablelands	30
Lateritic Plains.....	30
Hills and Plains of Maturely-Dissected Palaeozoic Rocks	30
Central Mountainous Zone	31
5. SOILS.....	32
Classification of the Soils.....	32
Description and Distribution of the Soil Groupings.....	32
(1) Lithosol.....	32
(2) Nomopodzol	32
(3) Leptopodzol.....	35
(4) Podzolic Deep Sand.....	35
(5) Solodic Soils.....	35
(6) Solonetzic Soils	36
(7) Red-Brown Earth.....	37
(8) Acidic Brown Clay	37
(9) Brown Soil of Heavy Texture.....	37
(10) Grey Soil of Heavy Texture	38
(11) Meadow Soil.....	39
Physical and Chemical Analyses	39
Particle Size Analysis	39

Reaction (pH)	39
Cation Exchange Capacity and Exchangeable Potassium	40
Phosphorus and Nitrogen	43
Soils of the Area and Land-Use	43
Category A	44
Category B.....	45
Category C.....	45
6. NATIVE VEGETATION.....	46
Classification of the Vegetation	46
Grassland.....	46
Heath	46
Wet Scrub	47
Dry Scrub	47
Dry Mallee.....	47
Heath Woodland.....	48
Short Woodland.....	49
Savannah Woodland.....	49
Shrub Woodland.....	49
Tall Woodland.....	49
Dry Sclerophyll Forest	50
Wet Sclerophyll Forest	50
Ecological and Land-Use Relationships of the Classification.....	51
PART III USE AND CONDITION OF THE LAND	55
7. PRESENT LAND-USE.....	56
Wool Growing and Beef Production	56
Pastures used by the Grazing Industries	56
Water Supply Catchments	58
Proclaimed Catchments	59
Wheat Growing	60
Forestry.....	61
8. SOIL EROSION.....	63
Erosion Hazard.....	63
Erosion in the Survey Area	63
Water Erosion.....	63
Catchment Salting	64
Distribution of water Erosion and Salting	65
Wind Erosion.....	65
PART IV A METHOD OF STUDYING THE LAND	66

List of Plates

Plate 1 – The Grampians rise abruptly from the flat plains and dominate the landscape for many miles. Mt William (3,830 ft) is in the centre of the photograph.	10
Plate 2 – The crescent or sickle shape of the lunette is well illustrated in this aerial photograph. The dark tone is caused by its dense cover of bracken.	26
Plate 3 – Sand dunes are scattered individually over the plains south of Horsham. Most of them are cleared and wind-eroded.....	27
Plate 4 – Mt Abrupt, near Dunkeld, clearly shows the features of the cuesta. The long dip slope on the left rises steadily to the summit and then gives way sharply to the precipitous scarp face. Below the scarp falls the gentle curve of the scree slope.	27
Plate 5 – The northern depositional plains were under the Tertiary Murray Sea. They now have gilgaied clay soils, and in many places woodlands of grey box and buloke as shown here.	30
Plate 6 – The Grampians Ranges stand out as high ridges of hard, resistant sandstones, and the intervening valleys have formed by the erosion of interbedded softer rocks. Between Mt William Range in the background and Serra Range in the foreground is the valley of the Wannon River.	31
Plate 8 – A cutting through a sand dune has exposed this profile of a podzolic deep sand.	36
Plate 9 – A solodic soil.....	36
Plate 10 – The surface of the clay subsoil in many solonetzic soils is shaped into domes, a feature that helps to distinguish these soils from solodic soils.	37
Plate 13 – A close-up of the shelf of a gilgaied grey soil of heavy texture.	38
It has a moderate structure of subangular blocky units, an important difference from the shelf soil in Plate 11....	38
Plate 14 – A puff in a gilgaied soil of heavy texture.	38
Plate 15 – In this harsh environment, with the upper dip slope of Mt William in the foreground, there is only a dry heath community with some stunted eucalypts	47
Plate 16 – A dry scrub of Grampians gum and heath species growing on a dip slope in the Grampians	48
Plate 17 – The dry mallee sub-formation clearly showing the understorey of broombush.	49
Plate 18 – An example of a heath woodland sub-formation with its well-developed heath layer. The eucalypts are long lef box and yellow gum.	49
Plate 19 – An example of the tall, dry sclerophyll forest. The trees are taller and have a better shape than they have in most parts of the ranges.....	50
Plate 20 – Rocklands dam and reservoir on the Glenelg River upstream from Balmoral.	59
This is the biggest storage in the scheme to distribute Grampians water northwards to the Wimmera and Mallee .	59
Plate 21 – There are limited areas of millable tress in the Grampians. This forest has been thinned to produce as many straight trees as possible.	60
Plate 22 – Areas of young red gum, as illustrated here, are of limited extent and this adds to their value as future sources of hardwood in western Victoria.	60
Plate 23 – Gullies are a sign that soil erosion is serious. Excessive clearing and over-grazed pastures are two contributing factors illustrated in this photograph.....	64
Plate 24 – One indication of serious erosion is deposits of silt overlying the original ground surface. Here, about two feet of silt is exposed in the wall of a gully. The A horizon of the original soil is the white band across the centre of the picture.....	64
Plate 25 – Most salt areas occur at the bases of hill slopes. The killing and clearing of trees on the higher land contributes to this. The example of salting shown has developed to the hardpan stage.....	65
Plate 26 – Wind erosion is uncommon in the survey area although individual examples can be severe, such as this blown-out sand dune near Horsham.....	65
Plate 27 – Three land-systems are shown in this photograph taken near Mt Zero.	68
Plate 28 – The East Wonwondah land-system is a flat or slightly undulating plain with gilgaied brown clays and woodlands of grey box and buloke.	73
Plate 29 – A sand pit has exposed the cross-section of a sand dune in the Warratong land-system. A heath woodland of yellow gum covers the area.	88

Plate 30 – In the Moora Valley land-system there are treeless heaths, as shown here, which indicate a clay subsoil close to the surface. The timber in the background is an apple box woodland growing in the deep, sandy podzols of a sand sheet	95
Plate 31 – From the air the three important components of Moora Valley land-system are readily identified. Areas marked A are red gum and yellow box woodlands growing in the oldest deposits of Plio-Pleistocene sands and clays. Areas marked B are the sand sheets of intermediate age covered with a heath woodland of apple box. Areas marked C are the youngest deposits and are recognised as treeless heaths.....	95
Plate 32 – Karabeal land-unit is a naturally treeless basalt plain with heavy clay soils. Wind breaks of sugar gums and pines have been planted.....	101
Plate 33 – The Dunkeld land-unit is a gently undulating plain with solodic soils and woodlands of red gum and swamp gum.....	102
Plate 34 – Two of the land units in Dundas land system. The flat tableland along the skyline is in Cavendish land-unit, and the gentle slopes forming the zone of creek dissection are part of Stapylton land unit. The remnant of a red gum woodland covers the entire landscape.....	104
Plate 35 – Most creeks and drainage lines in Dundas land system are salted as shown in this aerial photography of part of Skeleton Creek in the parish of Mooralla.	106
Plate 36 – Typical scene in Ararat land system, with Mt Chalambar (part of Ararat land unit) in the background and the gentler slopes of Moyston land unit in the foreground.....	112
Plate 37 – Rock outcrops are common in the granite area. In the foreground and mid-ground are rolling slopes of Lexington land unit and in the background are the lower slopes of the Eastern Black Range land unit.	117
Plate 38 – Mallee-broombush vegetation is characteristic of Darragan Mallee land-unit and is indicative of solonetzc soils which have a sandy A horizon overlying a clay subsoil at shallow depths.	122
Plate 39 – Most of the Grampians Ranges land-system consists of rugged sandstone cuestas with prominent ridges and near-vertical escarpments of rock. The forests have limited commercial value and serve mainly as protection forests for soil and water conservation.....	126
Plate 40 – A view of Serra Range form the Victoria Valley. The jagged, serrated outline of its ridge is clearly visible	127
Plate 41 – In the Grampians Plains land-system, gently sloping deposits of deep sand have accumulated at the foot of the ranges. They are covered with heath woodlands of brown stringybark, messmate and apple box.	129
Plate 42 – The deep deposits of sand that form the Grampians Plains land-system are marginal for land development. An unsuccessful attempt to develop a productive farm is shown here by the fence and partly cleared land reverting to scrub.....	130
Plate 43 – A carefully managed farm is easy to recognize. A good scatter of trees is retained over the paddocks, pastures are vigorous and protect the soil, and watering points for stock are in sufficient number.....	134
Plate 44 – Many underdeveloped areas such as this are still at the initial stage of burnt and ringbarked trees.	135

List of Tables

Table 1 – Percentage chances of receiving amounts or more of rain for each month for five representative stations	18
Table 2 – Average daily temperatures at Horsham, Ararat and Hamilton	18
Table 3 – Average 9.00 am saturation deficits and estimated evaporation at Horsham, Ararat and Hamilton	18
Table 4 - Percentage chances of receiving monthly rain equal to or greater than the effective amount for five representative stations. (Collated from the Wimmera and Glenelg Regional Reports, Central Planning Authority of Victoria).	19
Table 5 – Geomorphological units in the Grampians Survey	28
Table 6 – Soil groupings used in the Grampians Survey	33
The tops of three domes (or columns) are clearly exposed in this example.....	37

SUMMARY

The land covered by this survey is considered in two ways. First, for the area as a whole, an account is given of the major features of the environment significant for land-use, namely climate, parent material, topography, soils and native vegetation, together with the chief kinds of land-use and the forms of land deterioration. Second, an integrated assessment of the environmental features allows the recognition of land-systems and land-units, which are areas of land each with its characteristic pattern of features.

The area of the survey lies in central-western Victoria where the winters are cool and wet and the summers are hot and comparatively dry. The average annual rainfall varies from 171 inches on the northern plains to 35 inches in the central mountainous zone. There are flat depositional plains of unconsolidated sediments, undulating plains and hills formed on igneous and sedimentary rocks, dissected tablelands, and rugged sandstone mountains. The soil groups are considered in three broad categories, namely, deep infertile sands, heavy clays, and soils in which sandy loams overlie a clay subsoil. The most important forms of land-use are sheep grazing for fine wool on the plains, and the maintenance of water supply catchments in the mountains. Nineteen land-systems comprising forty-nine land-units have been mapped and described.

Soil erosion and salting are not common on most of the land. Where they do occur, overall treatment, including catchment improvement, is required to overcome these problems. Productivity of much of the land already developed could, with safety, be increased to that of the best properties. Most areas or undeveloped Crown lands have a low potential for economic pastoral production or softwood plantations. However, the cover of native vegetation on these areas performs a valuable function as catchment protection.
